

# Problem 3

Ha Vu Anh

First, we will prove that the segment connecting the midpoints of  $EE_1$  and  $EE_3$  passes through the midpoint  $FG$ , where  $F$  and  $G$  are the midpoints of  $AC$  and  $BD$ , respectively.

Let  $AD$  intersect  $BC$  at  $T$ ,  $AB$  intersect  $CD$  at  $S$ , and let  $TE$  intersect  $AB$  and  $CD$  at  $U$  and  $N$ . Let  $M_1M_3$  be the Gauss line of the quadrilateral  $AEBT$ ; then  $M_1M_3$  bisects  $TE$  at  $V$ .

Since  $(TE, UN) = -1$ , we have

$$VE^2 = VU \cdot VN, \quad (SU, AB) = (SN, DC) = -1,$$

so

$$SU \cdot SM_1 = SA \cdot SB = SD \cdot SC = SN \cdot SM_3.$$

Hence  $UM_1M_3N$  is cyclic  $\implies VT^2 = VU \cdot VN = VM_1 \cdot VM_3$ , so

$$\triangle VM_1T \sim \triangle VTM_3 \implies \angle VM_1T = \angle VTM_3.$$

Let  $R$  be the intersection of the two tangents at  $C$  and  $D$  of the circumcircle of  $ABCD$ . By Pascal's theorem applied to

$$\begin{pmatrix} A & D & C \\ B & C & D \end{pmatrix},$$

we obtain that  $TE$  passes through  $R$ .

Since  $BR$  is the symmedian of  $\triangle BCD$  (a well-known result), we have

$$\angle RBC = \angle M_3BD = \angle E_1BA$$

(as  $E_1$  is the isogonal conjugate of  $E$  in  $\triangle M_3AB$ ), so  $BE_1$  and  $BR$  are symmetric with respect to the internal bisector of  $\angle ABC$ , which is the external bisector of  $\angle TBA$ .

Similarly,  $AE_1$  and  $AR$  are symmetric with respect to the external bisector of  $\angle TAB$ , so  $E_1$  and  $R$  are two isogonal conjugate points in  $\triangle TAB$ , hence  $TE_1$  and  $TE$  are isogonal with respect to  $\angle BTA$ .

Also,

$$\triangle TAB \cup \{M_1\} \sim \triangle TCD \cup \{M_3\},$$

so  $\angle M_1TA = \angle M_3TC$ , implying  $TM_1$  and  $TM_3$  are isogonal in  $\angle BTA \implies \angle VM_1T = \angle M_3TE = \angle M_1TE_1$ , hence  $VM_1 \parallel TE_1$ .

Since  $V$  is the midpoint of  $TE$ ,  $VM_1$  bisects  $EE_1$ , so  $M_1M_3$  bisects  $EE_1$  at  $K$ . Similarly,  $M_1M_3$  bisects  $EE_3$  at  $Q$ .

We have

$$M_3G = AD/2 = M_1F, \quad M_3G \parallel AD \parallel M_1F,$$

so  $M_1FM_3G$  is a parallelogram, hence  $M_1M_3$  bisects  $FG$  at  $L$ , and thus  $KQ$  also bisects  $FG$  (Q.E.D.).

Returning to the problem, let  $E^*$  be the reflection of  $E$  across the midpoint of  $FG$ .

Consider a homothety centered at  $E$  with ratio 2 then  $E_1E_3$  passes through  $E^*$ . Similarly,  $E_2E_4$  passes through  $E^*$ , so  $W$  coincides with  $E^*$ .

Therefore,  $FG$  bisects  $EW$ , and since  $FG$  is the Newton-Gauss line of quadrilateral  $ABCD$ , the problem is proved.
